QuickLogic® PolarPro® 3
Device Data Sheet

Ultra-Low Power FPGA Combining Efficient Logic Cells with Embedded RAM and FIFO Blocks to Maximize Logic Density in Minimal PCB Space

Device Highlights

Ultra Low Power
- 55 μA static power consumption, suitable for smartphones, tablets, mobile enterprise devices and other power sensitive applications
- Prolongs device battery life

Small Form Factor Packaging
- 640 and 1,019 logic cell packages as small as 2.09 mm x 2.54 mm
- WLCSP, VFBGA, or die options available
- Designed for the most space-sensitive applications

Complete Customizable Solutions
- Allows offloading of computationally intensive applications
- Includes comprehensive software packages along with hardware

Efficient Logic Utilization
- Flexible logic cells, capable of two independent 3-input LUTs or a single 4-input LUT.
- Allows greater functionality in less PCB space

Embedded Standard Blocks
- Built in SRAM and FIFO controllers
- Enables data buffering and autonomous data transfers

Fast Time-to-Market
- QuickLogic designs and delivers complete Customer Specific Standard Product (CSSP) solutions, including hardware and software
- Uses QuickLogic’s existing library of Proven System Blocks (PSBs)
- Reduces development time and costs

Figure 1: PolarPro 3 Block Diagram
Flexible Reconfigurable Logic
- 1.2 V core voltage, 1.8/2.5/3.3 V drive capable I/Os
- Up to 64 kilobits of SRAM
- 55 µA standby current
- Up to 46 I/Os available
- 640 and 1,019 logic cell options
- Reconfigurable SRAM technology

Embedded Dual-Port SRAM
- Up to eight dual-port 8-kilobit high performance SRAM blocks
- True dual-port capability
- Embedded synchronous/asynchronous FIFO controllers
- Configurable and cascadable aspect ratio

Configurable I/O
- Configurable dual drive strength per GPIO
- Independent I/O banks capable of supporting multiple I/O standards in one device
- Bank programmable I/O standards: LVTTL, LVCMOS25 and LVCMOS18
- Week pulldown capability and input enables

Advanced Clock Network
- Multiple low skew clock networks
  - 5 programmable global clock networks
- Quadrant-based segmentable clock networks
  - 20 quad clock networks per device
Introduction

PolarPro 3 was specifically architected to meet the increasingly complex needs of mobile device OEMs. With special attention paid to efficient logic cell utilization, smallest size, and lowest power consumption during the design process, PolarPro 3 is the ideal solution for OEMs who require a configurable logic solution for their application. PolarPro 3 operates seamlessly with any processor available on the market today to address emerging connectivity, sensor control, and custom applications. QuickLogic combines PSBs and software drivers, along with customer-specific logic, to deliver CSSPs based on the exact requirements of our customers.

Table 1 summarizes the PolarPro 3 device family features.

Programmable Logic Architectural Overview

The QuickLogic PolarPro 3 logic cell structure presented in Figure 2 is a single register, multiplexer-based logic cell. It is designed for wide fan-in and multiple, simultaneous output functions. The cell has a high fan-in, fits a wide range of functions with up to 22 simultaneous inputs (including register control lines), and four outputs (three combinatorial and one registered). The high logic capacity and fan-in of the logic cell accommodates many user functions with a single level of logic delay.

The PolarPro 3 logic cell can implement:

- Two independent 3-input functions
- Any 4-input function
- 8 to 1 mux function
- Independent 2 to 1 mux function
- Inverted or non-inverted clock signal to flip-flop
- Single dedicated register with active high clock enable, set and reset signals
- Direct input selection to the register, which allows combinatorial and register logic to be used separately
- Combinatorial logic can also be configured as an edge-triggered master-slave D flip-flop
Figure 2: PolarPro 3 Logic Cell
RAM Modules

The PolarPro 3 family of devices includes up to eight 8 kilobits (9,216 bits) dual-port RAM modules for implementing RAM and FIFO functions.

RAM features include:
- Independently configurable read and write data bus widths
- Independent read and write clocks
- Inverted or non-inverted clock signals to read and write clock inputs
- Horizontal and vertical concatenation
- Write byte enables
- Selectable pipelined or non-pipelined read data

**Figure 3** shows the 8-kilobit Dual-Port RAM block.
Table 2 describes the RAM interface signals.

</tbody>
</table>

The read and write data buses of a RAM block can be arranged to variable bus widths. The bus widths can be configured using the RAM Wizard available in QuickWorks, QuickLogic’s development software. The selection of the RAM depth and width determines how the data is addressed.

The RAM blocks also support data concatenation. Designers can cascade multiple RAM modules to increase the depth or width by connecting corresponding address lines together and dividing the words between modules. Generally, this requires the use of additional programmable logic resources. However, when concatenating only two 8-kilobit RAM blocks, they can be concatenated horizontally or vertically without using any additional programmable fabric resources.

For example, two internal dual-port RAM blocks can be concatenated vertically to create a 1024x18 RAM block or horizontally to create a 512x36 RAM block. A block diagram of horizontal and vertical concatenation is displayed in Figure 4.

Figure 4: Horizontal and Vertical Concatenation Examples

### True Dual-Port RAM

PolarPro 3 Dual-Port RAM modules can also be concatenated to generate True Dual-Port RAMs. The True Dual-Port RAM module’s Port1 and Port2 have completely independent read and write ports and separate read and write clocks. This allows Port1 and Port2 to have different data widths and clock domains from each other. It is important to note that there is no circuitry preventing a write and read operation to the same address space at the same time. Therefore, the designer must ensure that the same address is not read from and written to simultaneously, otherwise the data is considered invalid. Likewise, the same address should not be written to from both ports at the same time. However, it is possible to read from the same address.

Figure 5 shows an example of a 1024x18 true dual-port RAM.
Table 4 describes the true dual-port RAM interface signals.

Embedded FIFO Controllers

Every 8-kilobit RAM block can be implemented as a synchronous or asynchronous FIFO. There are built-in FIFO controllers that allow for varying depths and widths without requiring programmable fabric resources. During asynchronous operation, the FIFO works in a half-duplex fashion such that PUSH is on one clock domain and POP is on another clock domain. The DIR signal allows the FIFO PUSH and POP signal directions to reverse. Refer to Table 6 for details on the signal directions. It is important that FIFO pointers are flushed after DIR is switched to reset the FIFO pointers.

The PolarPro 3 FIFO controller features include:

- x9, x18 and x36 data bus widths
- Independent PUSH and POP clocks
- Independent programmable data width on PUSH and POP sides
- Configurable synchronous or asynchronous FIFO operation
- 4-bit PUSH and POP level indicators to provide FIFO status outputs for each port
- Pipelined read data to improve timing
- Option for inverted or non-inverted Async_Flush input

</table>
FIFO Synchronous Flush Procedure

Both PUSH and POP domains are provided with a flush input signal synchronized to their respective clocks. When a flush is triggered from one side of the FIFO, the signal propagates and re-synchronizes internally to the other clock domain. During a flush operation, the values of the FIFO flags are invalid for a specific number of cycles (see Figure 7 and Figure 8).

As shown in Figure 7, when the Fifo_Push_Flush asserts, the Almost_Full and PUSH_FLAG signals become invalid until the FIFO can flush the data with regards to the Push clock domain as well as the Pop clock domain. After the Fifo_Push_Flush is asserted, the next rising edge of the Pop clock starts the Pop flush routine.

Figure 7 illustrates a FIFO Flush operation. After the Fifo_Push_Flush is asserted at 2 (PUSH_Clk), two POP clock cycles (11 and 12) are required to update the POP_FLAG, and PUSH_FLAG signals. The Almost_Empty signal is asserted to indicate that the push flush operation has been completed. On the following rising edge of the PUSH_Clk (7), the PUSH_FLAG is accordingly updated to reflect the successful flush operation.

![Figure 7: FIFO Flush from PUSH Side](image-url)
Figure 8 illustrates a POP flush operation. After the **Fifo_Pop_Flush** is asserted at 2 (POP_Clk), two PUSH clock cycles (11 and 12) are required to update the **POP_FLAG** and **PUSH_FLAG** signals. The **Almost_Empty** signal is asserted to indicate that the pop flush operation has been completed. On the following rising edge of the **POP_Clk** (7), the **POP_FLAG** is updated accordingly to reflect the successful flush operation.

![Figure 8: FIFO Flush from POP Side](image)

**Figure 7** and **Figure 8** are only true for this particular PUSH-POP clock frequency combination. The clock frequency and phase difference between POP_Clk and PUSH_Clk can cause an additional flush delay of one clock cycle in either domain because of the asynchronous relationship between the two clocks.

### FIFO Asynchronous Flush

Aside from the synchronous flush controls, there is an asynchronous flush signal named **ASYNC_FLUSH**. This signal is tied directly to the PUSH and POP pointers without any deglitching circuitry. The designer can add deglitching circuitry if desired.

### Distributed Clock Networks

#### Global Clocks

The PolarPro 3 clock network architecture consists of a 2-level H-tree network as shown in **Figure 9**. The first level of each clock tree (highlighted in red) spans from the clock input pad to the global clock network and to the center of each quadrant of the chip. The second level spans from the quadrant clock network to the column clock network, and then to every logic cell inside that quadrant. There are five global clocks in the global clock network, and five quadrant clocks in each quadrant clock network. All global clocks drive the quadrant clock network inputs.
The quadrant clocks output to column clock buffers, which can be dynamically disabled at the column level. Column clock buffers can be implemented in Verilog, VHDL, and schematic designs by instantiating the column clock buffer macro, CAND. **Figure 10** shows the schematic representation of the CAND macro. The global clocks can drive RAM block clock inputs and reset, set, enable, and clock inputs to I/O registers. Furthermore, the quadrant clock outputs can be routed to all logic cell inputs.
The five global clock networks can either be driven directly by clock pads or internally generated signals. These global clocks go through 2-input global clock muxes located in the middle of the die. A diagram of a 2-input global clock mux is shown in Figure 11.

**Figure 11: Global Clock Structure**

![Global Clock Structure Diagram]

**NOTE:** Select lines for the global clock and quadrant clock muxes are static signals and cannot be changed dynamically during device operation.

**Figure 12** illustrates the quadrant clock 2-input mux.

**Figure 12: Quadrant Clock Structure**
**GPIO Cell Structure**

The GPIO features include:

- Direct or registered input with input path select
- Direct or registered output with output path select
- Direct or registered output enable with OE path select
- Input buffer enable to reduce power
- Configurable pull-down control
- Inverted or non-inverted clock signal to flip-flops
- Two drive strength options

*Figure 13* is a diagram of the PolarPro 3 GPIO cell.
With bi-directional I/O pins and global clock input pins, the PolarPro 3 device maximizes I/O performance, functionality, and flexibility. All input and I/O pins are 1.8 V, 2.5 V, and 3.3 V tolerant and comply with the specific I/O standard selected. For single ended I/O standards, the corresponding VCCIO bank input specifies the input tolerance and the output drive voltage.

Table 10 describes the GPIO interface signals.

**Programmable Weak Pull-Down**

A programmable weak pull-down controller is also available on each GPIO. The I/O pull-down eliminates the need for external resistors.
PolarPro 3 Configuration Loading

The PolarPro 3 family of devices are reconfigurable. The configuration of a PolarPro 3 must be loaded each time the device is powered on. As shown in Figure 14, the PolarPro 3 provides two interfaces for configuring the logic cells and RAM blocks within the device. These two interfaces are SPI Master and SPI Slave.

Figure 14: Configuration Loading Block Diagram

SPI Modes of Operation

The configuration controller of the PolarPro 3 device can operate as a SPI Master or SPI Slave. When operating in SPI Master mode, PolarPro 3 devices read data from a Programmable Read-Only Memory (PROM). When operating in SPI Slave mode, PolarPro 3 receives data from a processor.

Operation in SPI Master mode or SPI Slave mode is determined by detecting either a logical high or low voltage on the SPI_CS_N pin upon de-assertion of SPI_RST_N.

- When SPI_CS_N is high, the PolarPro 3 SPI controller enters SPI Master mode.
- When SPI_CS_N is low, the PolarPro 3 SPI controller enters SPI Slave mode.

Once configuration is completed, the SPI_CS_N, SPI_MOSI, SPI_MISO, and SPI_CLK signals will become normal GPIO.
SPI Master Mode

In SPI Master mode (shown in Figure 15), SPI_RST_N must be asserted to hold the PolarPro 3 in a reset state until the PROM is fully powered up and ready to be read. Upon de-assertion of SPI_RST_N, the PolarPro 3 is set to SPI Master mode and will then take control of the SPI pins, and start initiating the required SPI commands.

Figure 15: SPI Master Mode

Configuration loading of the PolarPro 3 requires a PROM of adequate size (at least 1 Mbit). The PolarPro 3 SPI Master SPI clock frequency can operate at 4 MHz or 16 MHz during configuration. Once configuration is complete, the dual purpose SPI I/O pins can be used as normal GPIO. It is important to note that the VCCIO of the SPI pins for programming and normal operation must match the VCCIO of the PROM.

Upon completion of the loading, the PROM can be placed in a deep power down mode. To put the PROM into deep power down mode, the SPI Master sends a power down command after the last byte of data is received. Once the SPI pins switch to normal GPIO, and the PROM is in a deep power down mode, care must be taken to ensure that the PROM is not woken up unintentionally.

The PROM loading file used to program the external flash is generated by QuickLogic’s QuickWorks software tools. The configuration data is constructed to work with the corresponding commands from the PolarPro 3 SPI Master.
SPI Slave Mode

When the PolarPro 3 is powered up in SPI Slave mode (shown in Figure 16), the SPI Master takes control of the SPI pins. To initiate the data transfer, the SPI Master must assert the SPI_RST_N signal low for at least 20 ns to ensure the PolarPro 3 state machine is reset.

The configuration bit file, required for specifying the SPI Master commands, is generated by QuickLogic’s QuickWorks software tools. The resulting binary file combined with software drivers supplied by QuickLogic can be used for configuration loading of the PolarPro 3.

Configuration Verification Check Sum

To achieve higher system robustness, PolarPro 3 uses a checksum algorithm to guarantee data integrity. Upon receiving the data from the PROM, a check sum mechanism is used to ensure the PolarPro 3 configuration and embedded RAM data is intact. The final checksum is compared to those in the PROM checksum. If the checksums match, the CFG_DONE pin will go high. If the check sum does not match, the configuration controller retries configuration up to five times.

NOTE: Ensure that the SPI_MOSI and SPI_MISO pins are placed correctly. If these two signals are swapped, the CFG_DONE signal will still assert high and appear as if the device was configured correctly. However, it indicates that the request to configure the device with no information is completed.

More details on programming PolarPro 3 devices are located in the PolarPro 3 Configuration Loading User Guide.

SPI Timing Characteristics

The SPI specifications are provided in Table 18 through Table 23.

Table 18: SPI Master Timing

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Slow SPI_CLK</td>
</tr>
<tr>
<td>t_MFC_MIN</td>
<td>Minimum time from de-assertion of CFG_RST_N to the first SPI_CLK rising edge.</td>
<td>115 µs</td>
</tr>
<tr>
<td>t_MSU_MIN</td>
<td>Minimum setup time that the SPI Master output data will give before a SPI_CLK sampling edge.</td>
<td>105 ns</td>
</tr>
</tbody>
</table>

When operating as the SPI Master, the PolarPro 3 initially reads an external SPI flash device using a slow clock (~4 MHz). After reading one byte, it determines whether it will switch over to use the fast clock (~16 MHz) or not. This improves configuration time by a factor of four for SPI flash devices that can support the speed.

Table 19: SPI Master SPI_CLK Timing

<table>
<thead>
<tr>
<th>SPI Mode</th>

</tr>
<tr>
<td>( t_{GSKEW} )</td>
<td>Global delay clock skew</td>
<td>1.8 ps</td>
<td>4.1 ps</td>
</tr>
</tbody>
</table>

Power-Up Sequencing

Figure 19 shows an example where all VCCIO = 3.3 V. When powering up a PolarPro 3 device, VCC and VCCIO rails must take 40 µs or longer to reach their maximum values. Ramping VCC and VCCIO faster than 40 µs can cause the device to behave improperly. It is also important to ensure VCC precedes VCCIO. In the case where VCCIO ramps up prior the VCC, additional current will be drawn. SPI_RST_N should not be asserted until 250 µs after VCC reaches its full voltage level.
Power Consumption

QuickLogic’s ultra low power reconfigurable logic is ideal for implementing connectivity solutions, custom logic and processor interfaces. The quiescent current can be as low as 55 µA. The dynamic power consumption varies depending on the operating conditions and what functions are used in the logic cells. Contact your QuickLogic Customer Solution Architect (CSA) for specifics related to your use case.

Moisture Sensitivity Level

Table 26 describes the solder composition characteristics.

Table 26: Solder and Lead Finish Composition

<table>
<thead>
<tr>
<th>Package Typea</th>
<th>Ball Count</th>
<th>Lead Type</th>
<th>PB-Free</th>

</tr>
</tbody>
</table>

a. WLCSP = Wafer Level Chip Scale Package
VFBGA = Very-thin Fine-pitch Ball Grid Array
Package Thermal Characteristics

The PolarPro 3 solution platform is available for Commercial (-20°C to 85°C Junction) temperature ranges.

Thermal Resistance Equations:
\[
\begin{align*}
\theta_{JC} & = \frac{(T_J - T_C)}{P} \\
\theta_{JA} & = \frac{(T_J - T_A)}{P} \\
\theta_{JAmax} & = \frac{(T_{Jmax} - T_{Amax})}{\theta_{JA}}
\end{align*}
\]

Parameter Description:
- \( \theta_{JC} \): Junction-to-case thermal resistance
- \( \theta_{JA} \): Junction-to-ambient thermal resistance
- \( T_J \): Junction temperature
- \( T_A \): Ambient temperature
- \( P \): Power dissipated by the device while operating
- \( P_{MAX} \): The maximum power dissipation for the device
- \( T_{JMAX} \): Maximum junction temperature
- \( T_{Amax} \): Maximum ambient temperature

**NOTE:** Maximum junction temperature \((T_{JMAX})\) is 125°C. To calculate the maximum power dissipation for a device package look up \( \theta_{JA} \) from Table 27, pick an appropriate \( T_{Amax} \) and use:
\[
P_{MAX} = \frac{(125°C - T_{Amax})}{\theta_{JA}}.
\]

<table>

PCB Design Guidelines

Figure 23: WLCSP – PCB Design Guidelines

Figure 24: VFBGA – PCB Design Guidelines
PCB Layout Guidelines

When designing a PolarPro 3 PCB, extreme care must be given to the following areas:

- **Device interface signals:** clock and other data lines that run between devices on the PCB.
- **Power going into the device from the connector:** the power lines to the PolarPro 3 device must be filtered to pass only low frequency signals of less than 100 kHz. The ground signals must have returned current during data transmission.
- **External clock circuit.**

Generic Layout Guidelines

The following generic guidelines are from QuickLogic for a board design that contains PolarPro 3 devices. PCB designers should consult internal PCB design rules and recommendations, as well as other device manufacturers, to produce a working PCB.

Important PCB design elements include:

- **Type of circuit** (analog, digital, etc.)
- **Board size**
- **Number of layers**
- **Pad stack sizes**
- **Hole sizes**
- **Layer thickness**
- **Board thickness**
- **External connections**
- **Mounting holes**
- **Supply and ground layer thickness**
- **Component details with specifications**

Important design rules are:

- **Power distribution and coupling**
- **Critical signal paths**
- **IR [Current (I) x Resistance (R)] drops in signal and power traces**
- **Impedance control**
- **Pad/land geometries**
- **Trace width/spacings**
- **Plated/unplated hole sizes**
- **Part placement constraints**
Partitioning

The following guidelines are recommended for system partitioning:

- Divide the system into subsystems for placement. The division is used for layout partitioning of circuitries. Group components belonging to a functional block together.
- Isolate sensitive circuits (such as clocks and analog supplies) from noisy sources (such as high transition signals and power regulators).
- Separate analog power supplies from digital power supplies.

Placement

A system with a PolarPro 3 is comprised of a set of interacting elements responding to inputs to produce outputs. Good placement for logical data flow is important to keep the number of layers to a minimum.

The following guidelines are recommended for placement of components:

- For highly-sensitive circuits, place the critical components first to produce minimum trace-length.
- For less-critical circuits, arrange the components in the order of the signal flow to minimize the overall connection length.
- For components that have many connecting points, place these components first and group the remaining ones around them.
- For components with a fixed position (such as connectors), place these components first followed by components that are connected to the fixed components.
- Place the larger components (such as main devices) first. Place the smaller components (such as capacitors and resistors) between the larger components.
- Place components in rows or columns for good viewing.
- Place decoupling capacitors as close as possible (preferably adjacent) to the power pins of the device for maximum effectiveness.
Routing

The following guidelines are recommended for routing:

- Select the shortest interconnection length, especially for high frequency circuits (see Figure 25).

![Figure 25: Shortest Tracing Examples](image)

- Place traces with a minimum angle of 60 degrees (see Figure 26).

![Figure 26: Trace Angle Examples](image)

- Place parallel traces at the same angle to ensure uniformity, and eliminate the variance in the traces spacing.
- Distribute the spacing equally when one or more traces pass between pads or other conductive areas. To obtain maximum spacing, place traces perpendicular to a narrow passage.
- Distribute traces widely over the available area to avoid issues in manufacturing (i.e., do not space parallel running traces closely).
- Avoid unwanted bunching.
- Match signal impedance for all high-speed signals.
- Ensure that power lines are as thick as possible. Check the current requirements for the line.
- Ensure that the ground traces are always two times wider than the power traces.
- Distribute the routing pattern equally between the various layers of the PCB to achieve uniform plating in the manufacturing process.
• Route adjacent signal layers orthogonally to each other.
• Place ground or power planes to isolate signal layers when possible.
• Route traces directly to a connector pad without line branching to prevent reflections and impedance changes.
• Use curves or two 45° turns to avoid minor line reflections.
• Avoid line-width changes that can affect trace impedance.
• Make pads with soldered signal traces tear-dropped at the pad junction.

**Power**

Switching power regulators are noisy and can cause noise-coupling issues if placed close to sensitive areas on the PCB. Keep these circuits away from the sensitive traces, clock circuits and connectors.

**Clock Routing**

The following guidelines are recommended for clock routing:

• Use series terminator resistors to eliminate reflections. Obtain the final value by looking at the waveform using a high-speed oscilloscope to obtain minimum distortion on the signal.
• Use the 3W spacing rule when routing clock traces from one device to another to minimize cross-talk (see Figure 27).

![Figure 27: Clock Traces Spacing](image)

• Do not use 90° angles for bending.
• Include guard traces (ground) to surround the clock signal if possible.
• Place clock routing on an internal layer without stubs.

**High-Speed Differential Pair**

The following guidelines are recommended for high-speed input and output signal layout:

• For low-swing signals (≤300 mV), place the device as close to the driving source as possible (such as the flexible printed circuit or processor) to minimize the cross-talk, impedance mismatch, and differential noise pick-up. Keep the total trace-length <4 inches.
• Traces must always be matched lengths.
- Route the pair as close together as possible for noise rejection.
- Trace impedance must be 100 Ohm ± 10% to produce a 50 Ohm ± 10% pair.
- Signals must not have extra components to maintain signal integrity.

**Vias**

The following guidelines are recommended for via usage:

- Increase the clearance around the via to minimize capacitance.
- Minimize the number of vias per signal connection. Each via introduces discontinuities in the signal transmission line and increases the chance to pick up interference from other layers of the PCB.
- Avoid using a through-hole via as a test point if possible.

**Isolations**

Isolation is referred to as the separation between power and ground planes. The following guidelines are recommended for isolation:

- Isolate between digital and analog power planes.
- Do not route traces across planes (see Figure 28). This can cause a broken RF path for the return signal, which can result in severe EMI issues. Route high-speed sensitive signals parallel to solid power or ground planes.

![Figure 28: Routing Over Isolation Planes](image)

- Fill unused areas of a layer with copper and connect to ground planes using vias.
- Do not overlap planes between layers. These overlap areas can produce unwanted capacitance that passes RF emissions between the planes.
- Do not route signals over the slot-plane (see Figure 29).
Electrostatic Discharge (ESD)

The following guidelines are recommended for ESD:

• Provide ESD protection for PCB handling. The typical provision is an ESD strip around the board. The strip must connect to the PCB ground plane.
• Apply ESD protection to all connectors. The ground of the connector body must be connected to the PCB ground plane.

Layout Guidelines Specific to the PolarPro 3

Critical Signals

The following guidelines are recommended for the layout of critical signals:

• Keep the PolarPro 3 reference clock circuits as close to the device as possible.
• Follow the minimum spacing rules for reset lines from adjacent signals on the same and adjacent layers.
• Keep reset lines away from noisy sources (such as long clock traces, high energy signals and fast transition edges signals).
• Keep interrupt lines away from noisy sources (such as long clock traces, high energy signals and fast transition edges signals).

Vias

Use via-in-pad for the layout of vias and device connections.

GPIOs

The following guidelines are recommended for the layout of GPIOs:

• Keep the number of vias as close to minimum (two) as possible.
Power

The following guidelines are recommended for the layout of power:

- Use the power island or plane as much as possible.
- If using a power trace to connect to the PolarPro 3 power pins, make the trace as wide as possible, and follow current requirements to prevent excessive IR drop.
- Since the number of capacitors for the design is at a minimum, place all of the capacitors as close to the power pins as possible.

Reducing the Number of PCB Layers

The cost-reduction requirements common to PCB design and manufacturing requires the PCB designer to look for a solution to produce PCBs at the lowest cost possible. This section discusses areas that a PCB designer needs to consider when using a PolarPro 3 in the system.

There are several factors that contribute to the cost of a bare PCB:

- Volume: the number of PCBs per run.
- PCB size: the smaller, the less costly.
- PCB material: readily available material is less expensive.
- Number of layers: thickness reduction and quicker manufacturing time.
- PCB shapes: odd shape and slots require more processes.
- Copper size and spacing: the dimension of pads and spacing demand better PCB producing equipment.
- Via: current PCB technology is capable to handle more advanced via types: blind, buried, etc. These require more manufacturing time which translates into a more costly PCB.

Work with the PCB manufacturer to understand the trade-offs between PCB cost and these factors before finalizing PCB specifications.

Device Placement

Placement of devices is critical for good flow to nets routing, thus reducing the number of layers required. The placement must follow the flow of data between components. Critical components must be placed first, followed by support components such capacitors. Less critical components are placed last.

Make sure the device orientation is correct. If the device is in the correct location, but with the wrong orientation, the intended result may not be achieved. Always choose the orientation that has the most signals flowing in the same direction. Crossing signals require multiple layers to complete routing.

Via Technology

While advanced via technologies are more expensive that regular thru-hole via, they can be used to improve layers routing. Use blind via and/or buried via for a design that has constraints on PCB size (thus requiring routing of a signal under the PolarPro 3). Using via-in-pad for PolarPro 3 pins that need internal layer connections.
Power and Ground Planes

Dedicated power and ground planes yield the best impedance control and zero IR drop. However, these dedicated planes increases the thickness, and layers count for the PCB.

To reduce the need for a dedicated power plane, use thick traces for power routing. The thickness must meet the current requirements and be as wide as space allows.

To reduce the need for a dedicated ground plane, provide guards around the traces for each layer and fill the rest of the layer with copper (see Figure 30). Where possible, provide vias to tie these ground islands on each layer together. While this grounding method is not effective for EMI and trace impedance control, it provides plenty of grounding for the logics.

Figure 30: Fill-In Ground Examples

PCB Size

While increasing the board size can increase the cost of the PCB, this increase can be offset by the reduction of layers. Increasing board size provides additional routing areas and room for parts placement.
